13. Development Timeline
14. Cost Structure (Commercial Stage Only)
15. Key Risks & Honest Notes
16. Immediate Next Steps

1. What Changed in This Revision

This revision responds directly to external review of the first draft. The core critique: the original plan was trying to build an ERP-scale product before proving the single core promise works. The changes below are structural, not cosmetic.

Area	Before	Now
Scope	7 modules built together across 4 phases	4-module MVP ships first; remaining modules moved to a deliberately parked backlog
Positioning	“Unified Wealth Dashboard”	“The operating system for your financial life” — implies ongoing intelligence, not a static view
Health Score	6 flat, unweighted metrics	4 named categories (Wealth, Protection, Efficiency, Future) — explainable, not just a number
Reports	Charts and tables only	Narrative sentences generated from the same data — reads like advice, not a spreadsheet
Intelligence	Analytics only	Proactive AI-style daily/weekly insights layered on top of analytics
Timeline	34 weeks, single track	Two tracks: MVP (10–14 weeks part-time) and full vision (9–15 months part-time)

2. Product Positioning

Category: not an expense tracker, and not just a dashboard aggregator — a personal financial operating system. Closest comparables (INDmoney, Kubera, Groww, Jupiter) all show data. The wedge is that this product interprets it.

Positioning line

“The operating system for your entire financial life — one place that watches every rupee you own and tells you what to do about it.”

Why this matters

A dashboard is a feature every competitor already has. An opinionated, explainable score that changes week to week and tells the user why is much harder to copy convincingly, because it requires getting the underlying rules right, not just wiring up more charts.

3. MVP Definition — What Ships First

Four modules only. Everything else is explicitly out of scope for v1, not forgotten — see Section 4.

- Dashboard & Net Worth — total net worth, assets, cash, monthly growth, all sourced automatically.
- Transactions — income and expense tracking via SMS import, plus manual entry, categorization, and basic budgets.

- Investments — stocks and mutual funds, portfolio allocation, and performance, sourced from CAS/CAMS statements.
- Financial Health Score — the four-category score described in Section 7, with weekly narrative reports.

The test for MVP scope: does this module change whether a user opens the app again next week? Insurance, tax, and goals are valuable but low-frequency — nobody checks their term insurance daily. Net worth, spending, and a score that moves are what create a habit loop.

4. Vision Backlog — Deliberately Parked

Real, valuable, and explicitly not built until the MVP has proven the core promise. Two tiers:

Near-term (post-MVP, pre-fundraise)

- Insurance tracking (self & family) with expiry reminders and coverage-gap analysis.
- Tax planning — deduction headroom, capital gains, regime comparison.
- Goals — SIP-linked progress tracking.

Long-term (post-funding, full “Wealth OS” vision)

- Credit score tracking, loans and EMI tracking.
- Gold, real estate, PF, NPS, crypto, ESOPs, pension.
- Family wealth view, will and nominee tracking, document vault.
- Subscription management and a financial calendar (renewals, SIPs, tax deadlines).

Do not design the data model around this long-term list yet. Architecting for 15 future asset types before validating the first 4 is the exact over-building trap this revision is correcting for. Revisit this list only after the MVP is validated or funded.

5. Staged Roadmap

Same four stages as before, but Stage 1 now targets the narrow MVP, not the full module set — which is what makes the timeline realistic.

Stage	Goal	Cost	Exit criteria
1. MVP Build	4-module app, fully working for your own finances	₹0 — self-hosted, on-device	You use it daily without reverting to spreadsheets/old apps
2. Demo to Users	Validate with 5–10 real users on the MVP	₹0 — same free-tier build	Unprompted repeat usage in week 2 without reminders
3. Fundraising / Pitch	Prove traction + defensibility to investors	Minimal — pitch deck, data room	Term sheet or committed angel funding
4. Full Platform	Vision backlog modules + multi-user + compliance	AA fees, hosting, legal, licensing	Paying subscribers cover infra cost

6. MVP Functional Specification

Four modules only — matching Section 3. Each includes its Stage 1 (free) data source; live-sync upgrades are noted but not built until Stage 4.

6.1 Dashboard & Net Worth

- Total net worth, assets, cash, and monthly growth trend, computed automatically from Modules 6.2 and 6.3 — no separate data source of its own.
- This is the screen a user sees first every time — it should load instantly from cached aggregates, not recompute live on every open.

6.2 Transactions

- Income and expense tracking via SMS-derived transactions (Android bank-sender templates) plus manual entry fallback.
- Merchant categorization with self-learning corrections, a review queue so auto-captured entries are confirmed before affecting the Dashboard, and basic monthly budgets per category.
- Stage 4 upgrade: Account Aggregator for real-time multi-bank sync and iOS parity.

6.3 Investments

- Stocks and mutual funds — holdings, allocation by type (equity/MF/gold/bonds/cash), and performance.
- Data source: your own CAS (CDSL/NSDL) and CAMS/KFintech mutual fund statement — free, monthly, covers every broker and AMC in one document.
- Stage 4 upgrade: live broker APIs (Kite Connect, Upstox) for real-time holdings instead of monthly statements.
- Sector look-through, foreign vs. domestic split, and mutual fund overlap detection are Near-term backlog, not MVP — ship basic allocation first, add these once the core loop is validated.

6.4 Financial Health Score

- The four-category score defined in Section 7, computed weekly from Modules 6.2 and 6.3 data, with the narrative report format defined in Section 8.

7. Financial Health Score v2 — Four Categories

The single most important feature in the product — the reason someone opens the app on a week nothing unusual happened. Restructured from six flat metrics into four named, explainable categories so a low score always comes with a reason, not just a number.

Wealth

- Net worth growth rate
- Savings rate
- Investment returns vs. benchmark

Protection

- Insurance adequacy (Near-term backlog — scored as neutral until Module is built)
- Emergency fund adequacy
- Debt-to-income ratio

Efficiency

- Idle cash sitting in low-interest accounts
- Mutual fund overlap (Near-term backlog)
- Expense leakage — recurring or anomalous spending

Future

- Goal progress (Near-term backlog — scored as neutral until Module is built)
- Retirement readiness
- Tax efficiency (Near-term backlog)

Overall score is a weighted combination of the four categories. In the MVP, categories that depend on backlog modules (Protection's insurance component, all of Future) are shown as “not yet tracked” rather than silently scored — an honest gap is more trustworthy than a fabricated number.

8. AI Insights & Narrative Reports

The original plan treated the Health Score and periodic reports as calculated outputs displayed in charts and tables. The same underlying data, expressed as sentences instead, is what makes the product feel like it is thinking rather than just counting.

Daily/weekly insight example

“Good morning, Sandhosh. This month you saved ₹18,200 — spending decreased 9%. Your SBI account has ₹1.2L sitting idle. Consider moving ₹80K to your emergency fund or investments.”

Periodic report example

“Your wealth increased by ₹42,000 this month. 60% came from investments, 40% from savings. Food expenses increased 18% — mainly dining out. You remain on track for your Europe goal.”

How this is built

- Not a general-purpose AI chat feature — a template engine that selects the right sentence structure based on which metrics moved most, then fills in real numbers from the same aggregates powering the Dashboard and Health Score.
- Rules-based and deterministic at MVP stage: no model cost, no hallucination risk, and every sentence is directly traceable to a real number — important given the SEBI-safe language constraint in Section 11.
- A genuine LLM-based layer (e.g. more conversational, follow-up-question-capable insights) is a Stage 4 upgrade once there is real usage data to ground it in and a budget to run it.

9. Technical Architecture

Stage 1 — personal, zero-cost

- Mobile: Flutter, on-device only — no backend server required.
- Local database: Drift (SQLite) — same pattern as your existing Khazana app.
- SMS parsing: on-device only, bank-sender templates stored as versioned local config so parsing rules can be updated without an app release.
- Statement parsing: Python/Node scripts to parse CAS/CAMS PDFs into structured holdings data, run manually or on a schedule.

Stage 4 — commercial, multi-user

- Backend: .NET 9, Clean Architecture, CQRS/MediatR — direct reuse of your current ERP stack experience.
- Database: PostgreSQL for financial records (ACID compliance matters here); Redis for caching computed aggregates (net worth, health score).
- Async processing: RabbitMQ for AA consent webhooks, SMS parsing queue, statement parsing jobs.
- Security: encryption at rest for financial data, tokenized broker credentials via OAuth refresh — never store raw credentials.

10. Data Sourcing — Free vs. Paid, by Module

Module	Free-tier approach	Paid-tier approach
Bank accounts	SMS parsing (Android) + manual entry	Account Aggregator — multi-bank, real-time, iOS-compatible
Brokerage / MF	Own CAS (CDSL/NSDL) + CAMS/KFintech statements, parsed monthly	Live broker APIs (Kite Connect, Upstox) + AA for MF
Insurance (backlog)	Manual entry	Manual entry — stays the same at every tier; no reliable API exists
Health Score / Reports	Pure calculation on existing data — always free	Deeper what-if modeling, predictive scenarios

For the MVP, the fully free stack — SMS parsing, CAS/CAMS statement parsing, on-device storage — is not a compromise; it is arguably the better architecture for a single user, since CAS/CAMS statements are more complete (every broker and AMC in one document) than any single paid API would provide.

11. Regulatory & Compliance (Commercial Stage)

These obligations begin only once the product handles other people's financial data commercially — not required for Stage 1 or Stage 2.

- DPDP Act 2023: privacy policy, explicit consent flows, data retention limits, full data-deletion capability on request.
- Account Aggregator / FIU registration: handled through the AA provider's TSP license (Setu/Finvu) with business KYC — no separate RBI license needed.
- SEBI — critical: any feature that suggests specific investment actions (“buy X,” “sell Y”) crosses into regulated investment advice and requires SEBI Registered Investment Advisor status. Keep all suggestions — including the AI narrative insights in Section 8 — informational and rule-based (“users with similar profiles typically...”) rather than personalized recommendations, unless RIA registration is pursued.
- A registered business entity (sole proprietorship or LLP at minimum) is needed to sign vendor agreements with AA providers, brokers, and a payment gateway.

12. Monetization Strategy

Tier	Indicative price	Includes
Free	₹0	1 bank via SMS, manual brokerage entry, MVP Health Score
Plus	≈ ₹99–199/month	Multi-bank AA sync, live brokerage API, insurance & goals (backlog modules)
Pro	≈ ₹299–499/month	Tax optimization, predictive goal modeling, priority support

Price points are indicative and should be benchmarked against current INDmoney/Kubera pricing before finalizing, since fintech subscription pricing shifts frequently.

13. Development Timeline

Two tracks, deliberately separated. Track A is what you should actually be estimating against right now. Track B only starts after Stage 3 funding or validated demand — treat it as directional, not a commitment.

Track A — MVP (part-time, solo)

Phase	Weeks	Deliverable
Foundation	1–4	Transaction data model (source/confidence/review fields), SMS parsing pipeline, manual entry, Dashboard shell
Investments	5–8	CAS/CAMS parsing, basic asset allocation, holdings view
Health Score & Narrative Reports	9–12	Four-category score (Section 7), weekly narrative report (Section 8)
Polish & Beta Prep	13–14	Bug fixes, onboarding flow, ready for 5–10 beta users

Track B — Full Vision (post-funding or validated demand)

Phase	Approx. duration	Deliverable
Near-term backlog	2–3 months	Insurance, tax, goals — the modules parked in Section 4
Monetization infra	1–2 months	Subscription billing, AA integration, live broker APIs
Compliance & launch	1–2 months	Privacy policy, DPDP review, SEBI-safe language audit, security audit, public launch
Long-term backlog	Ongoing	Credit score, loans, gold/real estate/PF/NPS/crypto, family wealth, document vault

Total for Track B, run sequentially part-time: realistically 9–15 months depending on polish level — this estimate assumes eventually building the full original scope, which is why it is now explicitly separated from the MVP commitment in Track A.

14. Cost Structure (Commercial Stage Only)

Item	Notes
Account Aggregator (Setu/Finvu)	Per-pull charges plus possible onboarding fee — confirm current quotes directly before committing
Kite Connect API	Small recurring subscription per Zerodha's published developer pricing
Backend hosting	Free tiers (Azure/Render/Railway/Supabase) sufficient until real user scale
Business registration & legal review	One-time — do not skip legal review of privacy policy and advisory language, given SEBI exposure
App store fees	One-time: \$25 Android; \$99/year iOS

15. Key Risks & Honest Notes

- Competitive intensity: INDmoney and Kubera are well-funded incumbents. The realistic pitch is a sharper wedge (the Health Score and AI narrative layer) or an eventual acquisition path, not out-scaling them directly — worth being clear-eyed about this when framing the fundraising ask.
- SEBI exposure is the single biggest regulatory risk in this product category — any advisory or AI-generated language must be reviewed carefully before commercial launch.
- SMS/notification-based capture is Android-only by OS policy (Apple blocks SMS access outright) — CAS/CAMS statement upload and email parsing are the practical cross-platform and iOS paths.
- Parsing accuracy will not be perfect on day one across every bank format — the review/confirm queue is what protects data integrity and user trust while coverage improves.
- Scope discipline is now the primary execution risk, not technology — the biggest threat to Track A's 14-week timeline is quietly pulling backlog modules back into the MVP before the core loop is validated.

16. Immediate Next Steps

- Finalize the transaction data model (add source, confidence_score, is_reviewed fields) — this is the foundation every MVP module depends on.
- Build the SMS parsing pipeline for your own banks first — fastest path to a genuinely useful daily-use app.
- Pull your own CAS and CAMS statements and build the parser — unlocks the Investments module at zero cost.
- Define the exact weights and thresholds for the four Health Score categories before building the narrative report engine, since every sentence in Section 8 depends on the score logic being right first.
